

**SCIENTIFIC COMMITTEE
SEVENTEENTH REGULAR SESSION**

Online Meeting
11 –19 August 2021

**OVERVIEW OF TUNA FISHERIES IN THE WESTERN AND CENTRAL PACIFIC
OCEAN, INCLUDING ECONOMIC CONDITIONS – 2020**

WCPFC-SC17-2021/GN-IP-1

Paper prepared by

Peter Williams¹ and Thomas Ruaia²

¹ Pacific Community (SPC), Ocean Fisheries Programme (OFP), Noumea, New Caledonia

² Pacific Islands Forum Fisheries Agency (FFA), Honiara, Solomon Islands

ABSTRACT

This paper provides a broad description of the major fisheries in the WCPFC Statistical Area (WCP-CA) highlighting activities during the most recent calendar year (2020) and covering the most recent summary of catch estimates by gear and species.

The provisional total WCP-CA tuna catch for 2020 was estimated at **2,668,063 mt**, around 320,000 mt lower than the previous record catch in 2019 (2,988,661 mt). The WCP-CA tuna catch (2,668,063 mt) for 2020 represented 80% of the total Pacific Ocean tuna catch of 3,354,965 mt, and 52% of the global tuna catch (the provisional estimate for 2020 is 5,101,520 mt).

The **2020 WCP-CA skipjack catch of 1,769,202 mt** was around 279,000 mt lower than the record in 2019 (2,041,738 mt). The **2020 yellowfin catch (643,251 mt)** was amongst the highest on record, but around 65,000 mt less than the previous record in 2017. The recent high yellowfin tuna catches are related to some extent to recent high catch levels from the “other” category (primarily small-scale fisheries in Indonesia). The provisional **WCP-CA bigeye catch (150,180 mt)** for 2020 was slightly lower than the recent ten-year average and amongst the lowest over the past two decades, but higher than the 2019 catch (136,511 mt). The provisional **WCP-CA albacore catch for 2020 (105,4304 mt)** was amongst the lowest catches over the last two decades and 43,000 mt lower than the record (148,051 mt in 2002). The provisional **south Pacific albacore catch in 2020 (69,931 mt)**, was the lowest since 2011 and around 23,000 mt less than the record catch taken in 2017 (93,835 mt).

The provisional **2020 purse seine catch of 1,916,118 mt** was the fifth highest on record, and around 185,000 mt lower than the record catch in 2019 (2,101,408 mt). The 2020 purse seine skipjack catch (1,447,342 mt; 76% of the catch) was a clear drop of around 250,000 mt on the record in 2019 (1,700,000 mt). The 2020 purse seine catch for yellowfin tuna (391,250 mt; 20% of the total purse seine tuna catch) was around 104,000 mt lower than the record catch in 2017 (495,649 mt) but still amongst the highest annual catches for this fishery. The provisional catch estimate for bigeye tuna for 2020 (74,145 mt) was amongst the highest over the past five years and a clear increase on the 2019 purse seine bigeye tuna catch (50,728 mt). The increased bigeye tuna catch in 2020 appears to be related to a higher number of associated sets (which account for a higher proportion of bigeye tuna catch) conducted in 2020 than in 2019.

The provisional **2020 pole-and-line catch (152,098 mt)** was lower than the 2019 catch (195,402 mt) and, at this stage, the lowest annual catch since the mid-1960s, due to reduced catches in both the Japanese and the Indonesian fisheries.

The provisional **WCP-CA longline catch (211,773 mt) for 2020** is the lowest catch since 1993 at this stage, acknowledging the negative impacts due to COVID-19 but also that coverage of available 2020 data is not yet complete.

The **2020 South Pacific troll albacore catch (4,772 mt)** was the highest catch since 2004 (5,389 mt). The New Zealand troll fleet (140 vessels catching 2,859 mt in 2020) and the United States troll fleet (21 vessels catching 1,913 mt in 2020) accounted for all of the 2020 albacore troll catch.

Market prices in 2020 were mixed with prices for purse seine caught product generally declining after their recent peak in 2017. Thai imports averaged \$1,359/mt over 2020, marginally lower (3%) than 2019 levels which were 24% lower than the 2017 average of \$1,782/mt. In contrast, Yaizu prices for pole-and-line caught skipjack increased by more than 50% compared with 2019.

Prices for longline caught yellowfin declined in 2020 except for Japanese fresh imports from Oceania which rose 10% to ¥1,073/kg. Prices for longline caught bigeye in 2020 also declined across the selected markets except for Japanese fresh imports from Oceania. Thai imports prices for albacore continued to

increase to reach a record level of \$3,958/mt in 2019 but dropped 11% to \$3,505/mt in 2020. Albacore prices continued to decline this year averaging \$3,311/mt over the period to May 2021.

The total estimated delivered value of the tuna catch in the WCP-CA declined 16% to \$4.9 billion in 2020. The purse seine fishery was valued at \$2.8 billion, a decline of 12% on 2019 and equivalent to 56% of the total value of the tuna catch. A significant decline was also seen with the value of the longline fishery which fell 28% to \$1.21 billion. In contrast, the value of the pole-and-line catch increased 3% to \$372 million primarily driven by the significant increase in the price of pole-and-line caught skipjack at Yaizu. The value of the catch by other gears declined 17% to \$591 million. The 2020 WCP-CA skipjack catch was valued at \$2.54 billion, the yellowfin catch at \$1.5 billion, the bigeye catch at \$576 million and the albacore catch at \$320 million.

Economic conditions in 2020 in the longline fishery were extremely difficult with longline fleets, in particular those based in PICs and supplying fresh export markets, severely impacted by the impact of COVID-19 and associated mitigation on air freight costs and the ability of operators to send their product to traditional markets. **Economic conditions for the tropical purse seine in 2020 were at their lowest level since 2015** as fish prices and catch rates declined despite lower fuel prices resulting from the Covid-19 pandemic. However, the index in 2020 remained significantly above its 20-year average as catch rates remained relatively high and fuel costs were relatively low.

1. INTRODUCTION

The tuna fishery in the Western and Central Pacific Ocean is diverse, ranging from small-scale artisanal operations in the coastal waters of Pacific states, to large-scale, industrial purse seine, pole-and-line and longline operations in both the exclusive economic zones of Pacific states and on the high seas. The main species targeted by these fisheries are skipjack tuna (*Katsuwonus pelamis*), yellowfin tuna (*Thunnus albacares*), bigeye tuna (*T. obesus*) and albacore tuna (*T. alalunga*).

This review provides a broad description of the major fisheries in the WCPFC Statistical Area (**WCP–CA**; see Figure 1), highlighting activities during the most recent calendar year – 2020. The review draws on the latest catch estimates compiled for the WCP–CA, found in Information Paper WCPFC–SC17–ST IP–1 (*Estimates of annual catches in the WCPFC Statistical Area – OFP, 2020*). Where relevant, comparisons with previous years' activities have been included, although data for 2020, for some fisheries, are provisional at this stage.

This paper includes sections covering the four target tuna species, as well as blue marlin (*Makaira mazara*), black marlin (*Istiompax indica*), striped marlin (*Kajikia audax*) and swordfish (*Xiphias gladius*) catch in the WCP–CA tuna fisheries and an overview of the WCP–CA tuna fisheries by gear, including economic conditions in the main fisheries. In each section, the paper makes some observations on recent developments in each fishery, with emphasis on 2020 catches relative to those of recent years, but refers readers to the SC17 National Fisheries Reports, which offer more detail on recent activities at the fleet level.

Additional tabular and graphical information that provide more information related to the recent condition of the fishery and certain WCPFC Conservation and Management Measures (CCMs) have been provided in an APPENDIX.

This overview now attempts to include brief summaries of several fisheries in the north Pacific Ocean, including those fisheries catching albacore tuna, Pacific bluefin tuna (*T. orientalis*), striped marlin and swordfish. Information on these fisheries may be expanded in future reviews, depending on the availability of more complete data.

2. TOTAL TUNA CATCH AND CATCH VALUE FOR 2020

Annual total catches of the four main tuna species (skipjack, yellowfin, bigeye and albacore) in the WCP–CA increased steadily during the 1980s and 1990s with the purse seine fleet clearly the dominant fishery in terms of catch volume. The increasing trend in total tuna catch continued through to 2009, followed by two years (2010–2011) of reduced catches, before returning to record levels in successive years over the period 2012–2014. Catches in the period 2015–2017 were lower than 2014 but increased again over the period 2018–2019 (Figure 2.1 and Figure 2.2).

The provisional total WCP–CA tuna catch for 2020 was estimated at **2,668,063 mt**, around 320,000 mt lower than the previous record catch in 2019 (2,988,661 mt). For 2020, the **purse seine fishery** accounted for a catch of **1,916,118 mt** (72% of the total catch), with **pole-and-line** taking an estimated **152,098 mt** (6%), the **longline fishery** an estimated **211,773 mt** (8%), and the remainder (15%) taken by troll gear and a variety of artisanal gears, mostly in eastern Indonesia and the Philippines. The WCP–CA tuna catch (2,668,063 mt) for 2020 represented 80% of the total Pacific Ocean tuna catch of 3,354,965 mt, and 52% of the global tuna catch (the provisional estimate for 2020 is 5,101,520 mt).

Figure 2.1 Catch (mt) of albacore, bigeye, skipjack and yellowfin in the WCP–CA, by longline, pole-and-line, purse seine and other gear types

Figure 2.2 Catch (mt) of albacore, bigeye, skipjack and yellowfin in the WCP–CA.

The **2020 WCP–CA catch of skipjack** (1,769,202 mt – 66% of the total catch) was around 270,000 mt lower than the record in 2019 (2,041,738 mt). The **WCP–CA yellowfin catch** for 2020 (643,251 mt – 24%) was a decline of around 50,000 mt on the relatively high 2019 catch (694,032 mt), although the past five years have produced the highest annual yellowfin catches on record. The **WCP–CA bigeye catch** for 2020 (150,180 mt – 6%) was higher than the catch in 2015, but lower than the recent ten-year average. The **2020 WCP–CA albacore¹ catch** (105,430 mt – 4%) was lower than the recent ten-year average, and clearly lower than the record catch in 2002 of 148,051 mt.

¹ includes catches of north and south Pacific albacore in the WCP–CA, which comprised 85% of the total Pacific Ocean albacore catch of 124,774 mt in 2020; the section 8.4 “Summary of Catch by Species – South Pacific Albacore” is concerned only with catches of south Pacific albacore (69,931 mt in 2020), which made up approximately 57% of the Pacific albacore catch in 2020.

The provisional **total WCP-CA tuna catch in 2020 was valued at around \$4.9 billion**, 16% lower than from the previous year. The purse seine fishery in 2020 was valued at \$2.8 billion, equivalent to 56% of the total value of the tuna catch. The value of the longline and the pole-and-line fishery in 2020 continue to decline to be at \$1.2 billion and \$372 million respectively while the catch by other gears was valued at \$591 million. The value of the longline fishery account for 25% of the total value of the tuna catch; pole-and-line fishery and the catch by other gears contributed 8% and 12% respectively.

Figure 2.3 Catch value of albacore, bigeye, skipjack and yellowfin in the WCP-CA, by longline, pole-and-line, purse seine and other gear types.

In 2020, the **value of the 2020 WCP-CA skipjack catch** was estimated to be around **\$US 2.54 billion**, 12% lower than for 2019 and accounted for 51% of the total value of the tuna catch. The **WCP-CA yellowfin catch in 2020 is estimated to be at \$1.5 billion**, a decline of 21% from the previous year. The **value of the WCP-CA bigeye catch was valued at around \$576 million** to be at its lowest level since 2003 and accounted for 12% of the total value of the tuna catch. The **WCP-CA albacore catch in 2020 declined by 28% to \$320 million** to be at its lowest level since 2016 driven by an 11% decrease in prices.

Figure 2.4 Catch value of albacore, bigeye, skipjack and yellowfin in the WCP-CA.

3 WCP-CA PURSE SEINE FISHERY

3.1 Historical Overview

During the mid-1980s, the purse seine fishery (400,000–450,000 mt) accounted for only 40% of the total catch but has grown in significance to a level now over 65% of total tuna catch volume (with more than 2,000,000 mt in 2014). The majority of the historic WCP-CA purse seine catch has come from the four main Distant Water Fishing Nation (DWFN) fleets – Japan, Korea, Chinese-Taipei and USA, which numbered a combined 163 vessels in 1992 (Figure 3.1.1) but declined to a low of 111 vessels in 2006 (due to reductions in the US fleet), before some rebound in recent years (up to 129 vessels in 2017 and 124 vessels in 2020²). The Pacific Islands fleets have gradually increased in numbers over the past two decades to a level of 137 vessel in 2020 (Figure 3.3.1). The remainder of the purse seine fishery includes several fleets which entered the WCPFC tropical fishery during the 2000s (e.g. China, Ecuador, El Salvador, New Zealand and Spain).

Figure 3.1.1 Number of purse seine vessels operating in the WCP-CA tropical fishery
(excludes Indonesia, Philippine and Vietnam domestic purse seine/ringnet fleets)

Figure 3.1.2 Purse seine catch (mt) of bigeye, skipjack and yellowfin and fishing effort (days fishing and searching) in the WCP-CA
(EFFORT: excludes Indonesia, Philippine and Vietnam domestic purse seine/ringnet fleets)

The total number of purse seine vessels was relatively stable over the period 1990–2006 (in the range of 180–220 vessels), but thence until 2014, the number of vessels gradually increased, attaining a record level of 308 vessels in 2015, before steadily declining since (to 267 vessels in 2020). Further declines occurred in 2020 with a significant reduction in vessels from one component of the US purse seine fleet. Table 4 in WCPFC-Sec & SPC-OFP (2021) provides a breakdown on purse seine vessel numbers, tuna catch and effort by fleet, set type and species in the tropical tuna purse seine fishery based on raised logsheet data.

The WCP-CA purse seine fishery is essentially a skipjack fishery, unlike those of other ocean areas. Skipjack generally account for 65–77% of the purse seine catch, with yellowfin accounting for 20–30% and bigeye accounting for only a small proportion – 2–5%. Small amounts of albacore tuna are also taken in temperate water purse seine fisheries in the North Pacific.

Features of the purse seine catch by species during the past two decades include:

- Annual skipjack catches fluctuating between 600,000 and 850,000 mt prior to 2002, a significant increase in the catch during 2002, with subsequent skipjack catches maintained well above 1,200,000 mt;

² The number of vessels by fleet in 1992 was Japan (38), Korea (36), Chinese-Taipei (45) and USA (44) and in 2020 the number of active vessels by fleet was Japan (36), Korea (27), Chinese Taipei (29) and USA (23). In 2020, there was an additional 36 vessels in the category less than 200 GRT which are a part of the Japanese offshore purse seine fleet but not included here.

- Annual yellowfin catches fluctuating considerably between 300,000 and 400,000 mt, with a significant catch (record) of 496,000 mt taken in 2017. The proportion of large yellowfin in the catch is generally higher during El Niño years and lower during La Niña years, although other factors appear to affect purse seine yellowfin catch;
- Increased bigeye tuna purse seine catch estimates, coinciding with the introduction of drifting Fish Aggregating Devices –FADs (since mid-late 1990s). Significant bigeye catch years have been 2011 (87,302 mt–record), 2013 (84,404 mt) and 2014 (81,430 mt) which correspond to years with a relatively high proportion of associated sets, increased bigeye tuna availability to the gear, and/or strong bigeye recruitment.

Total estimated effort shows the same increasing trend as the catch over time (Figure 3.1.2), with years of relatively higher catch rates apparent when the effort line is clearly lower than the top of the histogram bar (i.e. in 1998 and 2006–2009, 2014–2020).

3.2 Provisional catch estimates, fleet size and effort (2020)

The provisional **2020 purse seine catch of 1,916,118 mt** was the fifth highest on record, and around 185,000 mt lower than the record catch in 2019 (2,101,408 mt). The 2020 purse seine skipjack catch (1,447,342 mt: 76% of the catch) was a clear drop of around 250,000 mt on the record in 2019 (1,700,000 mt). The 2020 purse seine catch for yellowfin tuna (391,250 mt; 20% of the total purse seine tuna catch) was around 104,000 mt lower than the record catch in 2017 (495,649 mt) but still amongst the highest annual catches for this fishery. The provisional catch estimate for bigeye tuna for 2020 (74,145 mt) was amongst the highest over the past five years and a clear increase on the 2019 purse seine bigeye tuna catch (50,728 mt). The increased bigeye tuna catch in 2020 appears to be related to a higher number of associated sets (which account for a higher proportion of bigeye tuna catch) conducted in 2020 than in 2019.

Figure 3.2.1 compares annual purse seine effort and catches for the five main purse seine fleets operating in the tropical WCP–CA in recent years. The combined “main-fleet” effort was relatively stable over the period 2010–2014, before the clear decline in effort for 2015 and then relatively stable effort levels over the period 2016–2020. In contrast, catches have clearly trended upwards over this recent period, suggesting increased efficiency and, in some instances, better catch rates; the 2019 catch for the “main fleets” is consistent with the overall record catch and was also the highest ever. The decline in effort during 2015/2016 was related to several factors including reduced access to fishing areas for some fleets, economic conditions and simply a choice to fish in areas outside the WCPFC area. The higher catch levels over recent years (despite the slight decline in effort) is related to increases in efficiency, including how the fishing is conducted (i.e. strategy) during the prevailing environmental conditions, and the relative availability of skipjack tuna (the main target) to the gear in each year. The slight drop in effort from 2017 to 2020 appears to be primarily related to a decline in vessel numbers (Figure 3.1.1).

Figure 3.2.1. Trends in annual effort (top) and catch (bottom) estimates for the top five purse seine fleets operating in the tropical WCP–CA, 1996–2020.

The combined Pacific-Islands fleet has been clearly the most dominant in the tropical purse seine fishery since 2003 and unlike the other fleets shown in Figure 3.2.1, their recent catches continue to increase each year. There was a hiatus in the Pacific-Islands fleet development in 2008 (when some vessels reflagged to the US purse seine fleet) but catch/effort has picked up in recent years and catch by this component of the fishery was clearly at its highest level in last two years (2019 and 2020). The combined Pacific-islands fleet catch in 2020 (831,972 mt)

easily exceeded the combined catch from the other fleets shown in Figure 3.2.1 (combined 2020 catch for Japan, Korea, Chinese Taipei and USA was 683,950 mt) for the first time. The fleet sizes and effort by the Japanese and Korean purse seine fleets have been relatively stable for most of this time series. Several Chinese-Taipei vessels re-flagged in 2002, dropping the fleet from 41 to 34 vessels, with fleet numbers relatively stable since. Since 2014, the catch/effort by most of the non-Pacific Islands fleets have tended to decline while the catch/effort by the combined Pacific Islands fleet have continued to increase, related to the reflagging of vessels from these distant-water fleets.

The total number of combined Pacific-island fleet vessels has gradually increased over the past two decades, attaining its highest level in 2020 (137 vessels); increases in these years include the reflagging and chartering of vessels from the Asian fleets. The combined Pacific-islands purse seine fleet covers vessels fishing under the FSM Arrangement, bilateral agreements and domestically based vessels and comprises vessels from the Federated States of Micronesia (FSM; 27 vessels in 2020), Kiribati (25 vessels), Marshall Islands (11 vessels), Papua New Guinea (PNG; 38 vessels including their chartered vessels), Solomon Islands (11 vessels), Tuvalu (3 vessels) and Vanuatu (6 vessels). Nauru purse seine vessels (2) entered the fishery for the first time in 2018 and their fleet has now grown to 15 vessels fishing in 2020. The Cook Islands entered the purse seine fishery in 2019 with 1 newly flagged vessel.

The domestic Philippine purse seine and ring-net fleets operate in Philippine waters and, since 2013 (as was the case prior to 2010), in the high seas pocket between Palau, Indonesia, FSM and PNG; this fleet accounted for a catch in the range 55,000-90,000 mt annually in the period since 2013. Prior to 2013, the domestic Indonesian purse seine fleet accounted for a similar catch level to the Philippines domestic fishery but generally has not fished in high seas areas. During 2013, the Indonesian fleet catch increased substantially (215,582 mt) with more on-shore processing facilities and more vessels entering the fishery. However, the purse seine catch in 2015 (~56,000 mt) dropped considerably from this level, mainly due to the introduction of a ban on transshipment-at-sea for vessels not built in Indonesia (which is nearly all of the current fleet). The Indonesian purse seine catch recovered (214,605 mt in 2017) apparently due to increased catches by the smaller-scale purse seine component of this fleet, although in recent years, the catch has been around 135,000 mt. Prior to 2009, the domestic fleets of Indonesia and Philippines accounted for about 13-16% of the WCP-CA total purse seine catch, although this proportion has dropped below 10% since then.

Figure 3.2.2 shows annual trends in sets by set type (left) and total tuna catch by set type (right) for the major purse seine fleets. Sets on free-swimming (unassociated) schools of tuna dominate during recent years (67% of all sets for these fleets in 2020). The proportion of sets on drifting FADs in 2020 (29%) was higher than in 2019 (25%) perhaps related to the need to rely on this fishing strategy in the prevailing La Niña conditions. The number and proportion (1% in 2020) of sets on natural logs was clearly the lowest in the fishery for the major fleets and reflects a move away from this type of fishing, in line with the improvements in technology/efficiency involving drifting FAD use. Associated set types, particularly drifting FAD sets, generally account for a higher average catch per set than unassociated sets, so the percentage of catch for drifting FADs (for 2020 = 46%: Figure 3.2.2–right [red]) will be higher than the percentage of sets for drifting FADs (for 2020 = 29% : Figure 3.2.2–left [red]). In contrast, the catch from unassociated schools in 2020 was 52% of the total catch but taken from 67% of the total sets. Table 4 in WCPFC-Sec & SPC-OFP (2021) provides a more detailed breakdown of catch and effort by set type in 2000-2020 using available logsheet and observer data.

Figure 3.2.2 Time series showing the percentage of total sets (left) and total catch (right), by school type for the major purse seine fleets operating in the WCP-CA.

3.3 Environmental conditions

The purse seine catch/effort distribution in tropical areas of the WCP-CA is strongly influenced by El Niño–Southern Oscillation Index (ENSO) events (Figure 3.3.1). Figure 3.4.1 (left) demonstrates the effect of ENSO events on the spatial distribution of the purse seine activity, with fishing effort typically expanding further to the east during El Niño years and contracting to western areas during La Niña periods.

The WCP-CA fishery moved into El Niño conditions during 2014 which strengthened in 2015 to a level not experienced in the fishery for almost 20 years (i.e. since 1997/1998). El Niño conditions continued into the first half of 2016 but then abruptly moved to a neutral state by the middle of the year which presided over the fishery into 2017. La Niña conditions developed in late 2017 and continued into the early months of 2018, before transitioning through a neutral state which presided over the rest of 2018. Weak-moderate El Niño conditions developed in late 2018, leading into the middle of 2019, and then subsided later in the year to neutral conditions by the start of 2020. La Niña conditions gradually emerged in 2020 and had peaked by the 3rd-4th quarters 2020 before waning in the first quarter of 2021 to neutral conditions by mid-2021. The current outlook for the remainder of 2021 is a further move to La Niña conditions which will remain until early 2022.

Figure 3.3.1 Trends in El Niño Southern Oscillation Index (ENSO), 2005-2021

3.4 Distribution of fishing effort and catch

Despite the FAD closure for certain periods in each year since 2010, drifting FAD sets remain an important fishing strategy (Figure 3.4.1–right), particularly to the east of 160°E. The relatively high proportion of unassociated sets in the eastern areas (e.g. Gilbert Islands) was a feature of the fishery in 2015–2016 (i.e. corresponding to El Niño conditions). The move to ENSO-neutral conditions, then weak La Niña during 2017 into early 2018 resulted in more effort in the area west of 160°E (Figure 3.4.1–bottom left; Figure 3.7.3–right) compared to recent years, and a higher use of drifting FADs in the area east of 160°E (Figure 3.4.1–bottom left). By late 2018, weak El Niño conditions presided over the fishery and relatively high catches were taken in the eastern tropical areas, in and adjacent to the waters of Tokelau and the Phoenix Group (Figure 3.7.3). El Niño conditions continued into 2019 with purse seine effort extending further to the east compared to recent years (Figure 3.4.1) and very good catches were taken in a few concentrated areas of the eastern tropical waters (see Figure 3.7.3). The La Niña conditions experienced in 2020 resulted in a general westward shift of fishing effort compared to 2019.

Figures 3.4.2 through 3.4.6 show the distribution of purse seine effort for the five major purse seine fleets during 2019 and 2020. In general, the distribution of effort for each fleet in 2020 is similar to 2019 activities, although some fleets (combined Pacific Island and Korea) showed some westward shift in activities in 2020. The US fleet typically fishes in the more eastern areas and this was again the case during 2019/2020, with effort extended into the Phoenix and Line Islands, the Cook Islands, Tokelau and the adjacent eastern high seas areas with increasingly less effort west of 160°E. The difference in areas fished by the non-Pacific islands' fleets in 2019/2020 (Figures 3.4.2–3.4.5) is related to the areas they have access to and perhaps also related to fishing strategy (e.g. use of traditional fishing grounds, e.g. FSM, PNG and the Solomon Islands by the Japan fleet). During 2020, effort by the combined Pacific Islands fleet moved more to the western areas (e.g. higher proportion of effort in the PNG and Solomon Islands waters) compared to effort during 2019, no doubt related to the prevailing (La Niña) conditions.

Figure 3.4.1 Distribution of purse seine effort (days fishing – left; sets by set type – right), 2014–2020. (Blue–Unassociated; Yellow–Log; Red–Drifting FAD; Green–Anchored FAD).

3.5 Catch per unit of effort

Figure 3.5.1 shows the annual time series of nominal CPUE by set type and vessel nation for skipjack (left) and yellowfin (right). These trends are not standardised for environmental factors or factors that may relate to the efficiency of the fleets, e.g. technological improvements and increased vessel power, so therefore must be interpreted with caution. Recent reviews of the available logsheet data used to determine nominal CPUE highlight an apparent change in reporting behaviour, with a clear increase in the reporting of transit days (over days searching); since transit days are not included as purse seine effort (and days searching is included), this change will inevitably result in a positive bias in the nominal CPUE data presented herein.

Purse seine skipjack CPUE in 2020 for most fleets declined from the record levels experienced in 2019 when a combination of environmental conditions and strong recruitment were contributing factors to the high catch rates in that year. Over the entire time series, the trend for skipjack CPUE is clearly increasing, although, as noted, these graphs present nominal CPUE and do not consider the increase in fishing efficiency (often referred to as ‘effort creep’). A possible indicator of an increase in fishing efficiency is the gradual reduction in average trip length over time, which is apparent in the linear trend of VMS trip length, which is estimated to decrease from about 32 days in early 2009 to around 28 days by mid-2020 (Figure 3.5.3).

Yellowfin purse seine CPUE shows strong inter-annual variability and there is greater variation in CPUE among the fleets than for skipjack. Unassociated-set yellowfin CPUE appears influenced by ENSO variation in the WCP-CA, with CPUE generally higher during El Niño episodes. This is believed to be related to increased catchability of yellowfin tuna due to a shallower surface-mixed layer during these periods. Associated (log and drifting FAD) sets generally yield higher catch rates (mt/day) for skipjack than unassociated sets, while unassociated sets sometimes yield a higher catch rate for yellowfin than associated sets. The higher yellowfin CPUE from free-schools occurs when “pure” schools of large, adult yellowfin are more available to the gear in the more eastern areas of the tropical WCP-CA, and so account for a larger catch (by weight) than the (mostly) juvenile yellowfin encountered in associated sets.

The purse seine yellowfin CPUE for free-schools in 2020 declined sharply for the USA fleet which typically fishes in the eastern areas compared to the other ‘main’ fleets shown in these CPUE trends (refer to Figures 3.4.3–3.4.6). In contrast, yellowfin CPUE in 2020 increased slightly for those fleets with effort concentrated more in the western areas in 2020 (Pacific Islands fleet and Korea). Figure 3.6.2 shows that for unassociated sets the “pure” schools of large, adult yellowfin were not present in the east during both 2019 and 2020 compared to years just prior to 2019 (see Figure 8.2.4), perhaps related to the prevailing ENSO conditions and/or different fishing strategies related to market demands.

Yellowfin catch rates on drifting FADs clearly increased for the Pacific Islands, Korea, US and Chinese Taipei fleets during 2020, but the CPUE for the Japanese fleet declined; as for CPUE with unassociated sets, this trend is perhaps related to the respective areas fished. The long-term time series for yellowfin CPUE shows more inter-annual variability and overall, a flatter trend than the skipjack tuna CPUE. It is unknown whether these trends reflect an increasing ability to target skipjack tuna at the expense of yellowfin, or reflect a change in yellowfin abundance, given that fishing efficiency has increased.

The difference in the time of day that sets are undertaken is thought to be one of the main reasons why bigeye tuna are rarely taken in unassociated schools compared to log and drifting FAD schools, which have catch rates of this species an order of magnitude higher (Figure 3.5.2). The trends in estimated bigeye tuna CPUE since 2000 varies by fleet and set type with no clear pattern evident, but with drifting FADs accounting for the highest catches and most variability. The bigeye tuna CPUE levels in 2020 were clearly higher than the relatively low levels experienced during 2019 and perhaps related to a shallower thermocline in the eastern and central tropical areas with the restriction of the warm pool under La Niña conditions during 2020 (Figure 3.5.2 and 3.7.3).

Figure 3.5.3 shows the inverse relationship between monthly CPUE (total tuna catch (mt) per day) and average trip length estimates (from logsheets and VMS); logsheet trip length tends to fluctuate in synchrony with CPUE, with shorter trips corresponding to higher CPUE. Average trip length (from VMS data) generally compares well to average trip length (from logsheet data), but as logsheet coverage declines (e.g. early 2021), estimates from these two sources tend to diverge since available logsheets are probably not representative. The FAD closure

period each year (commencing in 2010) generally coincides with a decline in total tuna CPUE, with longer trips and apparent difficulties obtaining consistent catches from free-swimming schools. The pattern in high CPUE in the months immediately following the FAD closure periods is understood to be mainly due to the build-up of unexploited biomass which then becomes available through FADs. The drop in CPUE from late 2016 into the first 6-8 months of 2017 may simply be due to a return to conditions prior to the most recent El Niño of 2014–2016. For 2020, the total tuna CPUE was lower than average from the start of the year and into the FAD closure months but rebounded in late 2020 and into early 2021 (noting that fluctuations in catch levels are also influenced by economic conditions).

Figure 3.5.1 Skipjack tuna CPUE (mt per day–left) and yellowfin tuna CPUE (mt per day–right) by set-type, and all set types combined, for selected purse seine fleets fishing in the tropical WCP–CA.

Effort and CPUE were partitioned by set type according to the proportions of total sets attributed to each set type.

Thick black line for “All set types” represents the Pacific Islands purse seine fleets combined.

Figure 3.5.2 Estimated bigeye tuna CPUE (mt per day) by major set-type categories (free-school, log and drifting FAD sets) and all set types combined for Japanese, Korean, Chinese-Taipei and US purse seiners fishing in the tropical WCP-CA.

Effort and CPUE were partitioned by set type according to the proportions of total sets attributed to each set type.

Thick black line for “All set types” represents the Pacific Islands purse seine fleets combined.

Dashed, black line represents the linear trend on VMS Trip length. VMS Trip length axis (right) is inverted.

For 2020, only the full-fishery, mandatory FAD closure period (July–Sept) is shown and acknowledges that flag states must choose an additional two-month FAD closure period as per the requirements in CMM 2018-01 para. 17.

3.6 Species/Size composition of the catch

Figures 3.6.1 and 3.6.2 show the species and size composition of the purse seine catch for 2019 and 2020, by set type and broad area of the tropical fishery. Points of interest in the comparison of these graphs include:

- Larger tuna catches for both set-type categories in 2019 compared to 2020 for the tropical area east of 170°E, related to the different ENSO conditions in those years (for example, La Niña conditions in 2020 restricted the fishery to the western tropical areas);
- Slightly larger skipjack tuna in the area east of 170°E from associated sets in 2020 compared with 2019, but smaller skipjack tuna in the area west of 170°E from unassociated sets in 2020 compared with 2019;
- A higher proportion of the bigeye tuna in associated sets east of 170°E (compared to the west), and the presence of medium-size (70–90 cm) bigeye tuna during 2020, which was not evident in 2019;
- The absence of large yellowfin tuna in the unassociated set catch in the area east of 170°E in 2020, compared to unassociated set catch in the area west of 170°E.

3.7 Seasonality

Figures 3.7.1 and 3.7.2 show the seasonal average CPUE for skipjack and yellowfin tuna in the purse seine fishery for the period 2015–2020, respectively. Figure 3.7.3 shows the distribution of effort by quarter for the period 2015–2019 in comparison to effort by quarter in 2020. Prior to implementation of the FAD closure, the average monthly skipjack CPUE was generally highest in the first half of the year and slightly lower thereafter, which contrasts with the yellowfin CPUE, which was at its lowest during the first six months, but higher thereafter. This situation corresponds to the seasonal eastward extension of the fishery in the second half of the year, to an area where schools of large yellowfin are thought to be more available than areas to the west due to, *inter alia*, a shallower surface-mixed layer. The FAD closure implementation since 2009 has tended to reduce CPUE during those [FAD-closure] months, with relatively high catch rates experienced immediately following the last FAD-closure month.

The trend in monthly skipjack CPUE for 2020 was clearly below the 2015–2019 monthly average for all months Jan–June, demonstrating difficult fishing conditions. The monthly 2020 skipjack CPUE was then very consistent to average for the months July to October (FAD closure months), before two very good CPUE/catch months in Nov–Dec (as the only months above the average).

The monthly yellowfin CPUE for 2020 was higher than the 2015–2019 average in the first two quarters of 2020, with good yellowfin tuna catches experienced in PNG (Figures 3.7.2 and 3.7.3). The monthly yellowfin CPUE during the FAD closure months of 2020 was clearly below the 2015–2019 monthly average and some of the lowest monthly CPUE experienced in recent years, but as with the skipjack CPUE, rebounded in Nov–Dec 2020.

The quarterly extent of the warm pool (i.e. surface water $>28.5^{\circ}\text{C}$ on average) in 2020 compared to the average for 2015–2019 (Figure 3.7.3) shows that the La Niña conditions in the second half of 2020 restricted the warm pool to the western areas compared to the recent 5-year average (2015–2019). Relatively higher catches were taken in PNG in the 3rd quarter 2020 compared to the 2015–2019 average period (Figure 3.7.3), and by the 4th quarter 2020, catches were concentrated in the 0° – 5°S latitude band in PNG/Solomon Islands and on the fringe of the eastern extent of the warm pool in the Gilbert Islands, Tuvalu, Nauru and adjacent high seas (Figure 3.7.3).

3.8 Prices, catch value and overall economic conditions

3.8.1 Prices

Skipjack

Global skipjack prices have been on a downward trend since their recent peak in 2017. In 2019, the price of Thai imports (cost and freight–c&f) fell 15% to average \$1,401/mt and declined further by 3% to \$1,359 in 2020. However, the Yaizu purse seine caught skipjack prices (ex-vessel) rose 9% to average ¥157/kg (\$1,468/mt). In 2020 currency units (that is, adjusting for inflation³), Thai import and Yaizu purse seine caught USD skipjack prices were 12% and 8% lower than their 20-year averages respectively. From the period of January to May in 2021, Thai import purse seine caught skipjack prices averaged \$1,347/mt. Yaizu prices averaged around ¥152/kg (\$1,413/mt) over the period of January to June in 2021.

Bangkok market reports indicated that skipjack prices (4-7.5lbs, c&f) increased significantly in the first quarter of 2020 to \$1,500 in March before declining to be \$1,200/mt at the end of June. At the beginning of the second half of the year, skipjack prices rose significantly to \$1,625 in August before declining again to \$1,300 in December. In the first quarter of 2021, prices declined further to \$1,200 in January before increasing to \$1,350/mt at the end of June. The Bangkok skipjack (4-7.5lbs, c&f) price index over the year to June in 2021 was below that of the FAO Food Price Index which had increased significantly in the past year and was at its highest level since 2013. (Figure 3.8.2). Through May 2021, Thai import volumes were higher by 9% compared with 2019. This was supported by the positive consumption trend for canned tuna worldwide; demand for raw tuna and semi-processed cooked loins increased in 2020 from tuna canners in Southeast Asia and Europe.

Figure 3.8.1 Annual skipjack prices, Thai imports (c&f) and Yaizu (ex-vessel)

Note: *For the period January to June

Figure 3.8.2 FAO Food Price Index and Bangkok 4-7.5lbs skipjack price (c&f) index

³ Based on the US CPI as measured by the Bureau of Labor Statistics All Urban Consumers CPI (www.bls.gov/cpi/data.htm)

Yellowfin

Since 2017 Thai import prices (c&f) for yellowfin have continued to decline. In 2020, the Thai import price averaged \$1,682/mt, a decline of 11% from the previous year level while Yaizu purse seine caught yellowfin prices (ex-vessel) declined 13% to ¥221/kg (\$2,070/mt). In 2020 terms, both the Thai import prices and the Yaizu real prices were below their 20 year average by 12% and 19% respectively.

Figure 3.8.3 Annual yellowfin prices, Thai imports (c&f) and Yaizu (ex-vessel)

Note: *For the period January to May

The average prices over the period to the end of May 2021 were marginally higher than the levels seen in 2020 with Thai import prices averaging \$1,669/mt. Yaizu prices averaged to ¥184/kg (\$1,711/mt) over the period to the end of June 2021. In addition, in the first quarter of 2021, Thai import volumes were lower compared with 2020 levels, although the import volumes in May 2021 were 4% higher than in the same period in 2020.

3.8.2 Catch Value

The catch value of the purse seine tuna catch in the WCP-CA area for 2020 is estimated to be valued at \$2.8 billion, a decline of 12% (\$370 million) from 2018.⁴ This is around 32% lower than that seen in 2012 and 2013 when the value of the purse seine fishery catch was at least \$4 billion as a result of high prices for raw material for canning. The catch value in 2020 represents the 10th highest purse seine catch value level on record in nominal terms (unadjusted for inflation) since 1997.

Figure 3.8.4 Value of the WCPFC-CA purse seine fishery tuna catch by species

In addition, the decline in the value of the skipjack catch in 2020 to \$1.98 billion (72% of the total purse seine tuna catch value) was largely driven by the continued decline in prices. Equally, low yellowfin prices in 2020 saw the value of the yellowfin catch decline to \$679 million (25% of the total value of the purse seine catch) from \$694 million in 2019.

3.8.3 Economic Conditions in the tropical purse seine fishery

Economic condition indexes for the major WCPFC-CA tuna fisheries has been presented to SC for a number of years. These indexes assess economic conditions in a fishery based on relative fish price, fishing cost (excluding license and access fee payments) and catch rates over the past 20 years (that is, 1999-2018). Together, information from the three components is combined into a single value expressed as an index against the average value over the preceding 20 years, scaled to 100, and provides a relative measure of changes in economic conditions over

⁴ The delivered value of each year's catch is estimated as the sum of the product of the annual purse catch of each species, excluding the Japanese purse seine fleet's catch, and the average annual Thai import price for each species (bigeye was assumed to attract the same price as skipjack) plus the product of the Japanese purse seine fleet's catch and the average Yaizu price for purse seine caught fish by species. Thai import and Yaizu market prices were used as they best reflect the actual average price across all fish sizes as opposed to prices provided in market reports which are based on benchmark prices, for example, for skipjack the benchmark price is for fish of size 4-7.5lbs. In deriving these estimates, certain assumptions were made due to data and other constraints that may or may not be valid and as such caution is urged in the use of these figures.

time. Values below 100 suggest that the fishery is experiencing below average economic conditions, while values over 100 indicate periods in which economic conditions in the fishery are relatively favourable.⁵ It is important to note that the indexes relate to the fishery not the vessels operating within it and, as such, while favourable economic conditions may be indicative of the ability of the fishery to generate significant profits, they do not indicate which parties, e.g. vessel owners or coastal states, accruing these profits accrue.

The tropical purse seine fishery⁶ economic conditions index in 2020 was at its lowest level since 2015 as fish prices and catch rates declined despite lower fuel prices resulting from the Covid-19 pandemic. However, the index in 2020 remained significantly above its 20-year average as catch rates remained relatively high and fuel costs were relatively low. The index has consistently been above its 20-year average since 2012 except for 2014. Over this time there was considerable variation in the contribution of the different index components. For instance, in 2012, 2013 and 2017, the high index readings were driven primarily by high fish prices while high catch rates were the main driver between 2014 and 2016 and from 2018 to 2020.

Figure 3.8.5 Tropical purse seine fishery economic conditions component indexes

Figure 3.8.6 Tropical purse seine fishery economic conditions index (LHS) and variance of component indices against average (2000-2020) conditions (RHS)

⁵ Full details of the methodology used to derive the economic conditions indexes presented can be found in Skirtun, M. and Reid, C. 2018, Analyses and projections for economic condition in WCPO fisheries, WCPFC-SC14-2018 ST- IP-06, Busan, Republic of Korea, August 8-16.

⁶ The tropical purse seine fishery economic conditions index is based on the fishery that lies between 10°N and 10°S of the WPCFC-CA, excluding the waters of Indonesia, Philippines and Vietnam.

4 WCP-CA POLE-AND-LINE FISHERY

4.1 Historical Overview

The WCP-CA pole-and-line fishery has several components:

- the year-round tropical skipjack fishery, mainly involving the domestic fleets of Indonesia, Solomon Islands and French Polynesia, and the distant water fleet of Japan
- seasonal sub-tropical skipjack fisheries in the domestic (home) waters of Japan, Australia, Hawai'i and Fiji (although no recent activity in the last three fisheries)
- a seasonal albacore/skipjack fishery east of Japan (largely an extension of the Japanese home-water fishery).

Figure 4.1.1 Pole-and-line vessels operating in the WCP-CA
(excludes pole-and-line vessels from the Japanese Coastal and Indonesian domestic fisheries)

Economic factors and technological advances in the purse seine fishery (primarily targeting the same species, skipjack) have resulted in a gradual decline in the number of vessels in the pole-and-line fishery (Figure 4.1.1) and in the annual pole-and-line catch during the past 15–20 years (Figure 4.1.2). The gradual reduction in numbers of vessels has occurred in all pole-and-line fleets over the past decade. Pacific Island domestic fleets have declined in recent years – fisheries formerly operating in Fiji, Palau and Papua New Guinea are no longer active, only one vessel is now operating (occasionally) in Kiribati, and fishing activity in the Solomon Islands fishery during the 2000s was reduced substantially from the level experienced during the 1990s. Several vessels continue to fish in Hawai'i, and the French Polynesian *bonitier* fleet remains active (33 vessels in 2020), but an increasing number of vessels have turned to longline fishing. Vessel and catches from Indonesian pole-and-line fleet have also declined over recent years. There is continued interest in pole-and-line fish associated with certification/eco-labelling.

4.2 Catch estimates (2020)

The provisional 2020 pole-and-line catch (152,098 mt) was lower than the 2019 catch (195,402 mt) and at this stage, the lowest annual catch since the mid-1960s, due to reduced catches in both the Japanese and the Indonesian fisheries.

Skipjack accounts for the majority of the catch (~70–83% in recent years, but typically more than 85% of the total catch in tropical areas) and albacore (8–20% in recent years) is taken by the Japanese coastal and offshore fleets in the temperate waters of the north Pacific. Yellowfin tuna (5–16%) and a small component of bigeye tuna (1–4%) make up the remainder of the catch. There are only five pole-and-line fleets active in the WCPO (French Polynesia, Japan, Indonesia, Kiribati and Solomon Islands).

Figure 4.2.1 Pole-and-line catch in the WCP-CA

Japanese distant-water and offshore fleets (79,795 mt in 2020), and the Indonesian fleets (53,015 mt in 2020), account for nearly all of the WCP-CA pole-and-line catch

(99% in 2020). The catches by the Japanese distant-water and offshore fleets in recent years have been the lowest for several decades and this is no doubt related to the continued reduction in vessel numbers (although the vessel numbers have been stable at around 75-80 over the past 5 years). The Solomon Islands fleet recovered from low catch levels experienced in the early 2000s (only 2,773 mt in 2000 due to civil unrest) to reach a level of 10,448 mt in 2003. This fleet ceased operating in 2009 but resumed fishing in 2011 with catches generally around 1,000 mt (1,149 mt in 2020 from 4 vessels).

Figure 4.2.2 shows the average distribution of pole-and-line effort for the period 1995–2020. Effort in tropical areas is usually year-round and includes domestic fisheries in Indonesia and the Solomon Islands, and the Japanese distant-water fishery. The pole-and-line effort in the vicinity of Japan by both offshore and distant-water fleets is seasonal (highest effort and catch occurs in the 2nd and 3rd quarters). There was also some seasonal effort by pole-and-line vessels in Fiji and Australia during this period. The effort in French Polynesian waters is essentially the *bonitier* fleet. Effort by the pole-and-line fleet based in Hawai'i is not shown in this figure because spatial data are not available.

Figure 4.2.2 Average distribution of WCP-CA pole-and-line effort (1995–2020).

4.3 Prices and catch value

4.3.1 Prices

The WCP- CA pole-and-line fishery is dominated by the fleets of Japan and Indonesia, with small catches taken by the fleets of Solomon Islands and French Polynesia. The pole-and-line fishing by the Japanese fleet is seasonal with the period of southern skipjack pole-and-line fishing normally between the month of November and June and then both near shore albacore and eastern offshore skipjack mainly during the period from July to October.

The price of pole-and-line caught skipjack at Yaizu in 2020 averaged \$2,948/Mt, a significant increase of more than 50% compared with the previous year. Similarly, the price of catch in waters off and south of Japan averaged \$3,654/Mt (¥390/kg) and \$2,611/Mt (¥279) respectively. The price of skipjack taken in waters off Japan was more than double that seen in 2019 with the price of skipjack taken in the southern fishery 27% higher. Over the period to June 2021, the price for skipjack caught in waters off and south of Japan averaged ¥220/kg and ¥235/kg respectively and were lower than for the same period in 2020.

Significant declines in the volumes of pole-and-line caught skipjack into Yaizu port were also seen in 2020. Offloading volumes of skipjack caught in waters off and south of Japan, respectively declined 13% and 71% from 2019 levels.

4.3.2 Catch Value

In 2020, the value of the total catch in WCPFC pole-and-line fishery was estimated to be at \$372 million⁷, an increase of 3% on 2019 with the significant increase in the average unit prices compensating for the contraction in total catch. The value of the skipjack catch in 2020 increased by \$33 million (13%) to \$286 million (77% of the total pole-and-line tuna catch value). In 2020, albacore and yellowfin contributed \$63 million and \$21 million respectively.

Figure 4.3.1 Value of the WCPFC-CA pole-and-line fishery tuna catch by species

⁷ Delivered skipjack prices for the Japanese pole-and-line fleet are based on a weighted average of the Yaizu 'south' and 'other' pole-and-line caught skipjack prices. Delivered yellowfin price for the Japanese pole-and-line fleet are based on the Yaizu purse seine caught yellowfin price. All other prices are based on Thai import prices. All prices are converted into USD using representative exchange rates provided by the [IMF](#).

5 WCP-CA LONGLINE FISHERY

5.1 Overview

The longline fishery now accounts for only 8–10% of the total WCP-CA catch (OFP, 2021), but approaches the much larger purse seine catch in landed value. It provides the longest time series of catch estimates for the WCP-CA, with estimates available since the early 1950s. The total number of vessels involved in the fishery generally fluctuated between 3,000 and 6,000 for the period 1970–2004 (Figure 5.1.1), although for some distant-water fleets, vessels operating in areas beyond the WCP-CA could not be separated out and more representative vessel numbers for WCP-CA have only become available in recent years⁸. Total longline vessel numbers have slowly declined over the past 15 years, with the provisional estimate of 1,570 vessels in 2020 showing a 58% drop on vessel numbers in 2005 and a 7% drop on 2019 vessel numbers, mainly due to a decline in the category of non-Pacific Islands domestic fleets, but also no doubt due to the impacts of COVID-19.

The fishery involves two main types of operation –

- large (typically >250 GRT) **distant-water** freezer vessels which undertake long voyages (months) and operate over large areas of the region. These vessels may target either tropical (yellowfin, bigeye tuna) or subtropical (albacore tuna) species. Voluntary reduction in vessel numbers by at least one fleet has occurred in recent years;
- smaller (typically <100 GRT) **offshore** vessels which are usually **domestically-based**, undertaking trips of less than one month, with ice or chill capacity, and serving fresh or air-freight sashimi markets, or [albacore] canneries. There are several foreign offshore fleets based in Pacific Island countries.

Figure 5.1.1 Longline vessels operating in the WCP-CA

(Available data does not make the distinction between foreign “distant-water” and “offshore”)

The following broad categories of longline fishery, based on type of operation, area fished and target species, are currently active in the WCP-CA:

- **South Pacific offshore albacore fishery** comprises Pacific-Islands domestic “offshore” vessels, such as those from American Samoa, Cook Islands, Fiji, French Polynesia, Kiribati, New Caledonia, PNG, Samoa, Solomon Islands, Tonga, Tuvalu and Vanuatu; these fleets mainly operate in subtropical waters, with albacore the main species taken. Two new entrants, Tuvalu and Wallis & Futuna, joined this category during 2011, although the latter fleet has not fished recently. Vessel numbers have stabilised in recent years, but they may also vary depending on charter arrangements.
- **Tropical offshore bigeye/yellowfin-target fishery** includes “offshore” sashimi longliners from Chinese-Taipei, based in Micronesia, Guam, Philippines and mainland Chinese vessels based in Micronesia, and domestic fleets based in Indonesia, Micronesian countries, Philippines, PNG, the Solomon Islands and Vietnam.
- **Tropical distant-water bigeye/yellowfin-target fishery** comprises “distant-water” vessels from Japan, Korea, Chinese-Taipei, mainland China and Vanuatu. These vessels primarily operate in the eastern tropical waters of the WCP-CA (and into the EPO), targeting bigeye and yellowfin tuna for the frozen sashimi market.
- **South Pacific distant-water albacore fishery** comprises “distant-water” vessels from Chinese-Taipei, mainland China and Vanuatu operating in the south Pacific, generally below 20°S, targeting albacore tuna destined for canneries.
- **Domestic fisheries in the sub-tropical and temperate WCP-CA** comprise vessels targeting different species within the same fleet depending on market, season and/or area. These fleets include the domestic fisheries of

⁸ Since 2005, more detailed information on fleet/vessel number breakdown has been required through WCPFC reporting requirements and are therefore more representative of WCP-CA longline activity.

Australia, Japan, New Zealand and Hawai'i. For example, the Hawaiian longline fleet has a component that targets swordfish and another that targets bigeye tuna.

- **South Pacific distant-water swordfish fishery** is a relatively new fishery and comprises “distant-water” vessels from Spain and Portugal (one vessel started fishing in 2011).
- **North Pacific distant-water albacore and swordfish fisheries** mainly comprise “distant-water” vessels from Japan (swordfish and albacore), Chinese-Taipei (albacore only) and Vanuatu (albacore only).

Additionally, small vessels in Indonesia, Philippines and Vietnam use handline and small vertical longline gears, usually fishing around the numerous arrays of anchored FADs in home waters and more recently, fishing at night using intense lights to attract prey for the tuna (these types of vessels are not included in Figure 5.1.1). The commercial handline fleets target large yellowfin tuna which comprise the majority of their overall catch (> 90%). The WCP-CA large-fish (yellowfin target) handline fishery took approximately 35,000 mt in 2020 (see [Section 7.1](#)).

The WCP-CA longline tuna catch steadily increased from the early years of the fishery (i.e. the early 1950s) to 1980 (230,625 mt), but declined to 162,111 mt in 1984 (Figure 5.1.2). Since then, catches steadily increased over the next 15 years until the late 1990s, when catch levels were again similar to 1980. Annual catches in the longline fishery since 2000 have been amongst the highest ever, but the composition of the catch in recent years (e.g. ALB–37%; BET–28%; YFT–34% in 2020) differs from the period of the late 1970s and early 1980s, when yellowfin tuna contributed a higher proportion of catch (e.g. ALB–18%; BET–27%; YFT–54% in 1980).

Figure 5.1.2 Longline catch (mt) of target tunas in the WCP-CA

5.2 Provisional catch estimates and fleet sizes (2020)

The provisional WCP-CA longline catch (211,773 mt) for 2020 is the lowest catch since 1993 at this stage, acknowledging the negative impacts due to COVID-19 but also that coverage of available 2020 data is not yet complete (see Figure A2 in the [APPENDIX](#)). The COVID-19 restrictions played a role in the distribution of 2020 effort in the longline fishery, with more effort in the south Pacific Albacore fishery (Figure A3) than recent years, and a corresponding decline in effort in the tropical longline fishery (Figure A4). The *La Niña* conditions during 2020 may also have contributed to lower catches in the longline fishery, although further investigation would be required to confirm this hypothesis.

The WCP-CA albacore longline catch (78,470 mt – 37%) for 2020 was clearly lower than the recent ten-year average, and more than 25,000 mt lower than the record of 106,142 mt attained in 2010. The provisional bigeye catch (58,560 mt – 28%) for 2020 was slightly lower than the recent ten-year average, and well down on the bigeye catch levels experienced in the 2000s (e.g. the 2004 longline bigeye catch was 99,709 mt). The yellowfin catch for 2020 (72,357 mt – 34%) was a significant drop on the high catch level in 2019 (106,279 mt).

A significant change in the WCP-CA longline fishery over the past 10–15 years has been the growth of the Pacific Islands domestic albacore fishery, which has risen from taking 33% of the total South Pacific albacore longline

catch in 1998 to accounting for around 50-60% of the catch in recent years. The combined national fleets (including chartered vessels) mainly active in the Pacific Islands domestic albacore fishery have numbered more than 500 (mainly small “offshore”) vessels in recent years and catches are now at a similar level as the distant-water longline vessels active in the WCP–CA.

The distant-water fleet dynamics have continued to evolve in recent years, with catches down from record levels in the mid-2000s initially due to a reduction in vessel numbers, although vessel numbers for some fleets appear to be on the rise again in recent years, but with variation in areas fished and target species. The Japanese distant-water and offshore longline fleets have experienced a substantial decline in both bigeye catches (from 20,725 mt in 2004 to 3,559 mt in 2020) and vessel numbers (366 in 2004 to 66 in 2020). The Chinese-Taipei distant-water longline fleet bigeye catch declined from 16,888 mt in 2004 to 4,147 mt in 2020, mainly related to a substantial drop in vessel numbers (137 vessels in 2004 reduced to 82 vessels in 2020). The Korean distant-water longline fleet experienced some decline in bigeye and yellowfin catches since the period of highest catches 15–20 years ago in line with a reduction in vessel numbers – from 184 vessels active in 2002 reduced to 100 vessels in 2020.

In contrast, the China longline fleet catches of albacore tuna have been amongst the highest ever in recent years (this fleet continues to catch over 20,000 mt of albacore tuna in the WCP-CA in recent years).

With domestic fleet sizes continuing to increase as foreign-offshore and distant-water fleets decrease (Figure 5.1.1), this evolution in fleet dynamics no doubt has some effect on the species composition of the catch. For example, the increase in effort by the Pacific Islands domestic fleets has primarily been in albacore fisheries, although this had been balanced to some extent by the switch to targeting bigeye tuna (from albacore) by certain vessels in the distant-water Chinese-Taipei fleet almost a decade ago. More detail on individual fleet activities during recent years is available in the WCPFC–SC17 National Fisheries Reports.

5.3 Catch per unit effort

Time series of nominal CPUE provide a broad indication of the abundance and availability of target species to the longline gear, and as longline vessels target larger fish, the CPUE time series should be more indicative of adult tuna abundance. However, as is the case with nominal purse seine CPUE, the interpretation of nominal longline CPUE is confounded by various factors, such as the changes in fishing depth that occurred as longliners progressively switched from primarily yellowfin tuna targeting in the 1960s and early 1970s to bigeye tuna targeting from the late 1970s onwards. Such changes in fishing practices will have changed the effectiveness of longline effort with respect to one species over another, and such changes need to be accounted for if the CPUE time series are to be interpreted as indices of relative abundance.

Nominal CPUE graphs are provided in the other papers (see Hare et al., 2021; WCPFC_Sec & OFP, 2021), and this paper does not attempt to explain trends in longline CPUE or effective effort, as this is referenced and dealt with more appropriately in specific studies on the subject and CPUE standardisation papers regularly prepared as WCPFC Scientific Committee (SC) papers.

5.4 Geographic distribution

Figure 5.4.1 shows the distribution of effort by category of fleet for the period 2000–2020. Effort by the **large-vessel, distant-water fleets** of Japan, Korea and Chinese-Taipei accounts for most of the effort, but there has been some reduction in vessel numbers in some fleets over the past decade. Effort is widespread as sectors of these fleets target bigeye and yellowfin for the frozen sashimi market in central and eastern tropical waters, and albacore for canning in the more temperate waters (see Figure 5.4.3), mainly in international waters.

Activity by the **foreign-offshore fleets** from Japan, mainland China and Chinese-Taipei is restricted to tropical waters, targeting bigeye and yellowfin

for the fresh sashimi market; these fleets have limited overlap with the distant-water fleets. The substantial "offshore" effort in the west of the region is primarily by the Indonesian, Chinese-Taipei and Vietnamese **domestic fleets** targeting yellowfin and bigeye (the latter now predominantly using handline gear).

The growth in **domestic fleets** targeting albacore tuna in the South Pacific over the past decade has been noted; the most prominent fleets in this category are the Cook Islands, Samoa, Fiji, French Polynesia, Solomon Islands (when chartering arrangements are active), Tonga and Vanuatu fleets (Figure 5.4.2).

Figure 5.4.1 Distribution of longline effort (100s of hooks) for distant-water fleets (green), foreign-offshore fleets (red) and domestic fleets (blue) for the period 2000–2020.

(Note that distant-water effort for Chinese-Taipei and other fleets targeting albacore in the North Pacific is poorly covered)

Figure 5.4.2 Distribution of effort for south Pacific albacore-target DOMESTIC longline fleets

Figure 5.4.3 Distribution of effort for south Pacific albacore-target FOREIGN longline fleets

Figure 5.4.4 shows quarterly species composition by area for the period 2010–2019 and 2020. The majority of the yellowfin catch is taken in tropical areas, especially in the western parts of the region, with smaller amounts in seasonal subtropical fisheries. The majority of the bigeye catch is also taken from tropical areas, but in contrast to yellowfin, mainly in the eastern parts of the WCP–CA, adjacent to the traditional EPO bigeye fishing grounds. The albacore catch is mainly taken in subtropical and temperate waters in both hemispheres. In the North Pacific, albacore are primarily taken in the 1st and 4th quarters. In the South Pacific, albacore are taken year round, although they tend to be more prevalent in the catch during the 3rd quarter. Species composition also varies from year to year in line with changes in environmental conditions, particularly in waters where there is some overlap in species targeting, for example, in the latitudinal band from 0°–20°S. The decline in bigeye catches in the tropical central and eastern areas is evident when comparing the 2010–2019 quarterly averages (Figure 5.4.4 –left) with the 2020 catches (Figure 5.4.4 –right).

The 2020 data are considered preliminary for some fleets and despite the noted impacts due to COVID-19, it is clear there are gaps in the distribution of the catch by species in certain parts of the WCPFC-CA Area north of the equator (3rd and 4th quarters in particular). There is a clear change in species composition and catch volume by 10° latitude band for the area bounded by 0°–30°S, 150E°–170°W from the 2nd quarter 2020, with high catches of yellowfin tuna, to the 3rd quarter, when there are clearly high proportions of albacore tuna in the longline catch. Also noteworthy is the relatively high catches of albacore and bigeye tuna in the 4th quarter 2020 on the eastern fringe of the WCPFC Area, south of the equator (WCPFC-IATTC overlap area), a pattern observed in previous years.

Figure 5.4.4 Quarterly distribution of longline tuna catch by species, 2010-2019 (left) and 2020 (right)
 (Yellow–yellowfin; Red–bigeye; Green–albacore)

(Note that catches from some distant-water fleets targeting albacore in the North Pacific may not be fully covered; excludes the Vietnam HL/LL fishery)

5.5 Overall economic conditions, prices and catch values

5.5.1 Economic conditions

In recent years economic conditions indexes have been presented in this report for the southern and tropical longline fisheries along with the component indexes relating to catch rates, fish prices and fishing costs. The cost index is primarily based on fuel costs with other costs assumed to be constant in real terms. However, given the impact of the COVID19 pandemic and associated mitigation measures on air freight costs and the ability of operators to send their product to traditional markets, this assumption is no longer appropriate. In addition, as outlined in the following section, there was a divergence in the direction of price movements in 2020 between product forms with prices of fresh tunas tending to increase while prices of frozen product fell. Given these factors, the economic condition indexes for the longline fisheries have not been estimated for 2020. However, some general observations can be made.

Longline fleets, in particular those based in Pacific Island Countries (PICs) and supplying fresh export markets, have been severely impacted by COVID-19 and associated mitigation measures with fleets either having to tie up, ship frozen product by sea freight, or use high cost air freight charters. Some fleets have tied up for an extended period and, in the case of the fresh longline fleet based out of Guam, shut down operations. In addition, some ULT frozen longline vessels are also understood to have switched their operations to target albacore. This has led to an overall reduction of longline effort but with most of the reduction being seen in the tropical longline fishery. Effort in the tropical longline fishery⁹ in 2020 contracted to 191 million hooks, the lowest level since 1997 and 30% lower than both that of 2019 and the average over the 5-year period 2015-19.

In contrast in the southern longline fishery¹⁰, 2020 effort levels at 294 million hooks were just 6% lower than 2019 levels, the highest since 2013, and 7% higher than average 2015-19 levels. This effort level occurred despite the vessel tie ups, the decline in catch rates of over 20% since 2017 and a reduction in frozen albacore prices (prices for Thai frozen albacore imports were 11% lower over 2020 than in 2019) for of over 10%. It is interesting to note that in 2012, when catch rates in the southern longline fishery were at similar levels to those seen in 2019, effort levels declined by 28% over the following four years which may have contributed to catch rates rebounding in a lagged fashion, peaking in 2017 before effort once gain increased and catch rates declined.

5.5.2 Prices

There are a large number of markets and product forms in which longline caught tuna and billfish are sold. In this section trends for selected longline fishery related price data for yellowfin, bigeye, albacore, swordfish and striped marlin are provided.

Yellowfin

In 2020, yellowfin prices across all markets examined declined significantly except for Japanese imports of fresh yellowfin from Oceania which rose 10% to ¥1,073/kg. Yaizu longline caught prices declined 9% to ¥537/kg in 2020 from ¥588/kg in 2019. Fresh and frozen yellowfin prices at selected ports declined 5% to ¥854/kg and ¥602/kg respectively compared with the rises of around 30% seen in 2017 across all these markets.

Prices for fresh yellowfin imports into the US in 2020 marginally declined to \$9.89/kg from the previous year. In US dollar terms, a significant decline was seen with the yellowfin prices across all markets except for fresh imports from Oceania which saw an increase of 13% to \$10.05/kg. The Yaizu longline-caught yellowfin declined 7% to average to \$5.03/kg with fresh and frozen yellowfin prices at selected ports both declined 3% to \$8.00/kg and \$5.64/kg respectively from the previous year.

Following the significant declines of import volumes for fresh yellowfin into Japan and the US in 2020, primarily caused by the Covid-19 pandemic which resulted in some vessels supplying fresh markets laying idle, a further

⁹ Defined as the longline fishery between 10°N and 10°S in the WPCFC-CA excluding the waters of Indonesia, Philippines and Vietnam.

¹⁰ Defined as the longline fishery south of 10°S in the WPCFC-CA.

decline was seen of the Japan fresh imports by 33% over the period to May 2021. However, fresh imports into US over the period to May 2021 have slowly recovered and were higher than in the same period in 2020.

Figure 5.5.1 Japan (LHS, in Yen) and US (RHS, in USD) Yellowfin prices

Note: Japan fresh imports from Oceania are c.i.f prices, Yaizu and Japan selected port are ex-vessel prices and US imports are f.a.s prices. Frozen at selected ports excludes purse seine caught landings

Bigeye

Similarly to yellowfin prices, fresh bigeye prices declined in 2020, except for Japanese fresh bigeye imports from Oceania. The Japan selected ports fresh and frozen prices averaged ¥1,251/kg (-3%) and ¥831/kg (-15%) respectively while the price for fresh imports from Oceania rose 20% to ¥1,254/kg.

The US fresh bigeye import prices have continued to increase in recent years and in 2020, increased further by 6% to \$10.31/kg, the highest price on record. In US dollar terms, the 2020 selected ports fresh and frozen prices declined 1% and 13% to \$11.71/kg and \$7.78/kg respectively from the previous year. In contrast, the price for fresh imports from Oceania rose by 22% to \$11.75/kg in 2020.

Following the significant decline in import volumes into Japan and US in 2020 as a result of the Covid-19 pandemic, a further decline of 37% was seen with the Japan bigeye fresh imports over the first five months of 2021. The US fresh bigeye imports volumes over to the period of May 2021, although slightly higher than 2020 levels, remained relatively low compared to 2019 levels.

Figure 5.5.2 Japan (RHS, in Yen) and US (RHS, in USD) bigeye prices

Note: Japan fresh imports from Oceania are c.i.f prices, Japan selected ports are ex-vessel prices and US imports are f.a.s prices. Frozen at selected ports excludes purse seine caught landings

Albacore

US fresh albacore prices have been on an upward trend with the price (c&f) rising 10% in 2020 to average \$5.92/kg which is the highest on record. However, Thai frozen import and the Japan selected ports prices in 2020 came off their 2019 peaks to \$3.51/kg (-11%) and \$3.14/kg (-28%) respectively.

Import volumes for frozen albacore into Thailand in 2020 increase by 20% from the previous year and this may be due to, at least in part, the disruptions in longline caught yellowfin and bigeye markets resulting in some vessels shifting to targeting albacore. For the first five months of 2021, the import volumes although marginally lower than of 2020 levels remained high relative to 2019 levels. Following a significant decline of more than 50% of the US fresh import volumes in 2020, the import volumes declined further by 27% over the period to May in 2021 relative to same period in 2020.

Figure 5.5.3 Albacore prices in US dollars

Note: Thai frozen imports are c&f prices, Japan selected ports are ex-vessel prices and US imports are f.a.s prices.

Swordfish and striped marlin

The Japan fresh swordfish price across all markets declined in 2020. Fresh swordfish and striped marlin prices at selected Japanese ports fell 12% (to ¥960/kg) and 5% (to ¥532/kg) respectively in 2020 following a significant increase in 2019 in particular for fresh swordfish. Similarly, the US fresh swordfish declined 5% to average \$7.07/kg in 2020, its lowest level since 2005.

Figure 5.5.4 Japan (RHS, in Yeb) and US (RHS, in USD) swordfish and striped marlin prices

Note: Japan selected ports are ex-vessel prices and US imports are f.a.s prices.

5.5.3 Catch Value

The estimated delivered value of the longline tuna catch in the WCPFC area for 2020 is \$1.21 billion, equivalent to 25% of the total value of the WCPO tuna catch of \$4.86 billion. This represents a significant decline of \$483 million (-28%) on the estimated value of the catch in 2019.¹¹

In 2020, a significant decline was seen in the value of all target species. The value of yellowfin catch fell 31% to \$516 and bigeye catch value declined by \$131 million (-22%). Similarly, the catch value for albacore and skipjack catch declined significantly by \$117 million (-33%) and \$4.7 million (55%) respectively.

These declines were largely driven by the significant decline of 20% in the longline catch in 2020 which was primarily associated with the Covid-19 mitigation measures and resulted in some these longline vessels supplying fresh markets to stop operations. The low prices for longline caught yellowfin and bigeye in 2020 also contributed to the significant decline in the total value of the longline tuna catch seen in 2020.

Figure 5.5.5 Value of the WCPFC-CA longline fishery tuna catch by species

¹¹ For the yellowfin and bigeye caught by fresh longline vessels, it is assumed that 80% of the catch is of export quality and 20% is non-export quality. For export quality, the annual prices for Japanese fresh yellowfin and bigeye imports from Oceania are used, while it is simply assumed that non-export grade tuna attracted \$1.50/kg throughout the period 1997-2013. For yellowfin caught by frozen longline vessels the delivered price is taken as the Yaizu market price for longline caught yellowfin. For bigeye caught by freezer longline vessels, the delivered price is taken as the frozen bigeye price at selected major Japanese ports. For albacore caught by fresh and freezer longline vessels, the delivered prices is taken as the Thai import price. The frozen longline catch is taken to be the catch from the longline fleets of Japan and Korea and the distant water longline fleet of Chinese Taipei.

6 SOUTH-PACIFIC TROLL FISHERY

6.1 Overview

The South Pacific troll fishery is based in the coastal waters of New Zealand, and along the Sub-Tropical Convergence Zone (STCZ, east of New Zealand waters located near 40°S). The fleets of New Zealand and the United States have historically accounted for the great majority of the catch that consists almost exclusively of albacore tuna.

The fishery expanded following the development of the STCZ fishery after 1986, with the highest catch attained in 1989 (8,370 mt). Over the past decade, catches have declined to range from 2,000–4,000 mt, which are catch levels not been experienced since prior to 1988 (Figure 6.1.1). The level of effort expended by the troll fleets each year can be driven by the price conditions for the product (albacore for canning), and by expectations concerning likely fishing success.

Figure 6.1.1 Troll catch (mt) of albacore in the south Pacific Ocean

6.2 Provisional catch estimates (2020)

The 2020 South Pacific troll albacore catch (4,772 mt) was the highest catch since 2004 (5,389 mt). The New Zealand troll fleet (140 vessels catching 2,859 mt in 2020) and the United States troll fleet (21 vessels catching 1,913 mt in 2020) accounted for all of the 2020 albacore troll catch, although minor contributions have also come from the Canadian, the Cook Islands and French Polynesian fleets when their fleets were active in the past.

Effort by the South Pacific albacore troll fleets is concentrated off the coast of New Zealand and across the Sub-Tropical Convergence Zone (STCZ) – refer to Figure 6.2.1.

Figure 6.2.1 Distribution of South Pacific troll effort during 2019 (left) and 2020 (right)

7 OTHER FISHERIES

There are a number of other, mainly small-scale, fisheries in the WCP-CA that target the key tuna species, including handline gear that targets large yellowfin tuna, small-scale troll/hook-and-line fisheries, small-scale gillnet and a range of other artisanal gears. The following sections attempt to provide some information on some of these “other” fisheries.

7.1 Large-fish Handline Fishery

Large-fish Handline fisheries exist in the Philippines, Indonesia and Hawaii, where the target is essentially large yellowfin tuna (and also bigeye tuna in the case of Hawaii). In the Philippines and Indonesia, this fishery can be comprised of both small craft and larger vessels (> 24m or > 20GRT).

The larger vessels can have several small associated one-person boats (called *pakura* in the Philippines) used to fish in the vicinity of the larger vessel.

The vessels that target large yellowfin tuna with the handline gear are also referred to as “pump boats” in the Philippines. The general characteristics that distinguish the vessels targeting small-fish with the “hook-and-line” gear to those targeting large yellowfin tuna in the Philippines and Indonesia is that the latter fishery is conducted at night, at a depth typically greater than 50 metres with larger hooks. [However, this distinction is not always clear, for example, there are instances when small craft can target both large yellowfin at night and small tunas in the day within one trip]. Large yellowfin tuna dominate the catch from this gear type in the Philippines and Indonesia (typically $\geq 95\%$ of the total catch) and the catches are landed locally where it is processed and available for export or the high-end local markets.

Figure 7.1.1 WCP-CA large-fish Handline catch (mt) by species

Over the past two decades, annual catch estimates from the large-fish handline fishery have been in the range of 20,000–57,000 mt (Figure 7.1.1), although the estimates prior to 2014 are acknowledged to exclude the catches from the Indonesian fishery (that is, estimates for Indonesia have only been compiled from 2014 onwards). The 2020 catch was a clear decline on catches in recent years and understood to be mainly due to the impacts of COVID-19.

7.2 Small-scale troll and hook-and-line Fishery

The small-scale troll and hook-and-line fishery comprises small craft that, due to their size and concerns on safety, conduct trips that do not usually exceed one day and are restricted to coastal waters, rarely venturing beyond territorial seas and/or archipelagic waters (where relevant). The method of fishing is varied and includes trolling, and surface fishing in the vicinity of FADs with one or multiple hooks per line. Small skipjack and yellowfin tuna are the main species taken in this fishery and most coastal states in the tropical and sub-tropical WCP-CA have vessels in this fishery, with the highest catches reported from the Indonesia and the Philippines domestic fisheries, followed by Kiribati, Japan, French Polynesia and Tuvalu (catches from some countries, while only minor, have

Figure 7.2.1 WCP-CA troll / hook-and-line catch (mt) by species

in this fishery, with the highest catches reported from the Indonesia and the Philippines domestic fisheries, followed by Kiribati, Japan, French Polynesia and Tuvalu (catches from some countries, while only minor, have

yet to be compiled and provided to the WCPFC). The catches from this fishery are typically for subsistence or sold at local markets.

Over the past two decades annual catch estimates from the small-scale troll and hook-and-line fishery have been in the range of 120,000–300,000 mt (Figure 7.2.1), although the trends in some years may be a result of the lack of resources to compile or confirm estimates, rather than a change in the fishery. The increasing trend over the past decade may be related to improvements in estimates in some fisheries. The species composition tends to fluctuate with some years having a high proportion of small yellowfin tuna (e.g. in 2018 and 2019 small yellowfin tuna catch was estimated to at least 50% of the total tuna catch for this fishery).

7.3 Small-scale gillnet Fishery

The main small-scale gillnet fisheries operate in coastal waters of Vietnam and Indonesia, with smaller catches from this gear in Japan and in the archipelagic waters of the Philippines. This fishery targets skipjack tuna but also take small amounts of other pelagic species.

The available annual catch estimates (Figure 7.3.1) are probably only representative from 2013 onwards, when Indonesia first separated out the gillnet catch by species from their “other/unclassified gear” tuna catch estimates. The total tuna catch from the drift gillnet fishery has ranged from less than 40,000 mt to 64,000 mt over the past eight years.

Figure 7.3.1 WCP-CA small-scale gillnet catch (mt) by species

8. SUMMARY OF CATCH BY SPECIES

8.1 SKIPJACK

Total skipjack catches in the WCP–CA have increased steadily since 1970, more than doubling during the 1980s, and continuing to increase in subsequent years. Annual catches have exceeded 1.5 million mt in the last decade (Figure 8.1.1). Pole-and-line fleets, primarily Japanese, initially dominated the fishery, with the catch peaking at 380,000 mt in 1984. The relative importance of the pole-and-line fishery, however, has declined over the years primarily due to economic constraints. The skipjack catch increased during the 1980s due to growth in the international purse seine fleet, combined with increased catches by domestic fleets from Philippines and Indonesia (which have made up around 10% of the total skipjack catch in WCP–CA.

Figure 8.1.1 WCP–CA skipjack catch (mt) by gear

The 2020 WCP–CA skipjack catch of 1,769,202 mt was around 279,000 mt lower than the record in 2019 (2,041,738 mt). Catch in the **purse seine** fishery for 2020 (1,447,342 mt – 82%) was also well down on the 2019 record for that fishery, noting that the trend in purse seine skipjack catch typically drives the trends in overall skipjack catch. The **pole-and-line** catch for 2020 (121,530 mt – 7%) was a reduction on the 2019 catch level and amongst lowest catches since 1963, with reductions in both the Japanese and the Indonesian catches. The various “artisanal” gears in the domestic fisheries including Indonesia, Philippines and Japan took 195,767 mt in 2020 (11% of the total catch) which was lower than the recent 5-year average. The **longline** fishery accounted for less than 1% of the total catch.

Figure 8.1.2 Distribution of skipjack tuna catch, 1990–2020.

The eight-region spatial stratification used in stock assessment is shown.

The majority of the skipjack catch is taken in equatorial areas, and most of the remainder is taken in the seasonal domestic (home-water) fishery of Japan (Figure 8.1.2). The domestic fisheries in Indonesia (purse seine, pole-and-line and unclassified gears) and the Philippines (e.g. ring-net and purse seine) account for the majority of the skipjack catch in the western equatorial portion of the WCP–CA. Central tropical waters are dominated by purse seine catches from several foreign and domestic fleets. As mentioned in Section 3, the spatial distribution of skipjack catch by purse seine vessels in the central and eastern equatorial areas is influenced by the prevailing ENSO conditions.

The Philippines and Indonesian domestic fisheries (archipelagic waters) generally account for most of the skipjack catch in the 20–40 cm size range (Figure 8.1.3), although associated purse seine catch also contribute to this range (e.g. in 2014). Most of the WCP–CA skipjack catch (by weight) is in the range 40–70 cm (corresponding to 1–2+ year-old fish – Figure 8.1.4). Medium-large (60–70 cm) skipjack typically make up the greater proportion of the catch from unassociated, free swimming school sets. The overall purse seine skipjack size distribution in 2020 is different to 2019 (which was a record catch year), and more similar to 2017 (Figure 8.1.4). The skipjack size “structure” in the Philippine/Indonesia archipelagic fisheries has been relatively constant for a number of years (Figure 8.1.4 – yellow).

Figure 8.1.3 Annual catches (no. of fish) of skipjack tuna in the WCPO by size (2cm intervals) and gear type, 2014–2020.

(red–pole-and-line; yellow–Phil-Indo archipelagic fisheries; light blue–purse seine associated; dark blue–purse seine unassociated)

Figure 8.1.4 Annual catches (MT) of skipjack tuna in the WCPO by size (2cm intervals) and gear type, 2014–2020.

(red–pole-and-line; yellow–Phil-Indo archipelagic fisheries; light blue–purse seine associated; dark blue–purse seine unassociated)

8.2 YELLOWFIN

The total yellowfin tuna catch in the WCP-CA has slowly increased over time but since 1998, jumped to a new level with annual catches regularly exceeding 500,000 mt (Figure 8.2.1), mainly due to increased catches in the purse seine fishery. The 2020 yellowfin catch (**643,251 mt**) was amongst the highest on record, but around 65,000 mt less than the previous record in 2017. The recent high yellowfin tuna catches are related to some extent to recent high catch levels from the “other” category (primarily small-scale fisheries in Indonesia – provisional 2020 estimate for “Other” is 111,517 mt – 17% of the total catch).

The WCP-CA **longline** catch for 2020 (72,357 mt–11%) was the lowest catch since 1999 and less than 30,000 mt compared to the 2019 catch in this fishery; a decrease in effort in the broad area where yellowfin are mainly targeted (due to COVID-19) no doubt contributed to this decline. Since the late 1990s, the **purse seine** catch of yellowfin tuna (391,250 mt in 2020–61%) has accounted for about 3-5 times the **longline** yellowfin tuna catch.

The **pole-and-line** fisheries took only 11,600 mt during 2020 (~2% of the total yellowfin catch) which is the lowest since the 1970s but may be considered provisional at this stage.

Catches in the ‘**other**’ category are largely composed of yellowfin taken by various assorted gears (e.g. troll, ring-net, bagnet, gillnet, large-fish handline, small-fish hook-and-line and seine net) in the domestic fisheries of the Philippines and eastern Indonesia. Figure 8.2.2 shows the distribution of yellowfin catch by gear type for the period 1990–2020. As with skipjack, the great majority of the catch is taken in equatorial areas by large purse seine vessels, and a variety of gear types in the Indonesian and Philippine fisheries.

The domestic surface fisheries of the Philippines and Indonesia (archipelagic waters) take large numbers of small yellowfin in the 20–50 cm range (Figure 8.2.3), and their deep-water handline fisheries take smaller quantities of large yellowfin tuna (> 110 cm). In the purse seine fishery, smaller yellowfin are caught in log and FAD sets than in unassociated sets. A major portion of the purse seine catch is adult (> 100 cm) yellowfin tuna, to the extent that the purse seine catch (by weight) of adult yellowfin tuna is clearly higher than the longline catch. Most of the catch of large yellowfin tuna in the size range 120–140 cm from the purse seine unassociated sets is typically taken in the eastern tropical WCP-CA. There were lower catches of large yellowfin tuna from purse seine unassociated sets in the past two years (2019–2020) compared to the period 2016–2017, and only a small proportion of fish >130cm in the 2020 purse seine catch in contrast to the catch in years 2017–2019 (Figure 8.2.4). There are typically two modes of small fish (< 50 cm) and one mode of large fish (>100 cm from the handline gear) in the yellowfin catches from the Indonesia/Philippines domestic fisheries. Section 3.6 also provides some insights into the distribution of purse seine yellowfin catch by area and size.

Figure 8.2.1 WCP-CA yellowfin catch (mt) by gear

Figure 8.2.2 Distribution of yellowfin tuna catch in the WCP-CA, 1990–2020.

The nine-region spatial stratification used in stock assessment is shown.

Figure 8.2.3 Annual catches (no. of fish) of yellowfin tuna in the WCPO by size (2cm intervals) and gear type, 2014–2020.

Figure 8.2.4 Annual catches (MT) of yellowfin tuna in the WCPO by size (2cm intervals) and gear type, 2014–2020.
 (green–longline; yellow–Phil-Indo archipelagic fisheries; light blue–purse seine associated; dark blue–purse seine unassociated)

8.3 BIGEYE

The provisional **WCP-CA bigeye catch** (150,180 mt) for 2020 was slightly lower than the recent ten-year average and amongst the lowest over the past two decades, but higher than the 2019 catch (136,511 mt). The **WCP-CA longline** bigeye catch (58,560 mt) was clearly lower than the recent ten-year average. The provisional **WCP-CA purse seine** bigeye catch for 2020 was estimated to be 74,145 mt which was nearly 25,000 mt higher than in 2019 and slightly higher than the recent ten-year average (Figure 8.3.1). The WCP-CA purse seine bigeye catch has exceeded the longline catch for many of the past ten years. The purse seine and longline fisheries has accounted for an average of 89% of the total WCP-CA bigeye catch over the past ten years.

The **WCP-CA pole-and-line** fishery has generally accounted for between 1,000–10,000 mt (1–6%) of bigeye catch annually over the past decade. The "other" category, representing various gears (including troll) in the Philippine, Indonesia¹², Vietnam and Japanese domestic fisheries has fluctuated between an estimated 4,000–21,000 mt (3–14% of the total WCP-CA bigeye catch) over the past two decades.

Figure 8.3.1 WCP-CA bigeye catch (mt) by gear

Figure 8.3.2 shows the spatial distribution of bigeye catch in the Pacific for the period 1990–2020. The majority of the WCP-CA catch is taken in equatorial areas, both by purse seine and longline, but with some longline catch in sub-tropical areas (e.g. east of Japan and off the east coast of Australia). In the equatorial areas, much of the longline catch is taken in the central Pacific, continuous with the important traditional bigeye longline area in the eastern Pacific.

Figure 8.3.2 Distribution of bigeye tuna catch, 1990–2020.

The nine-region spatial stratification used in stock assessment for the WCP-CA is shown.

¹² Bigeye tuna estimates in the Indonesian troll fishery were provided for the first time for 2013 but have subsequently (since 2017) been included in the "other" category.

As with skipjack and yellowfin tuna, the domestic surface fisheries of the Philippines and Indonesia (archipelagic waters) take relatively large numbers of small bigeye in the range 20–60 cm (Figure 8.3.3). The longline fishery clearly accounts for most of the catch (by weight) of large bigeye in the WCP–CA (Figure 8.3.4). This contrasts with large yellowfin tuna, which (in addition to longline gear) are also taken in significant amounts from unassociated (free-swimming) schools in the purse seine fishery and in the Philippines handline fishery. Large bigeye tuna are very rarely taken in the WCPO purse seine fishery and only a relatively small amount come from the handline fishery in the Philippines. Bigeye tuna sampled in the longline fishery are predominantly adult fish with a mean size of ~130 cm FL (range 80–170+ cm FL). Associated sets account for nearly all the bigeye catch in the WCP–CA purse seine fishery with considerable variation in the sizes from year to year, but the majority of associated-set bigeye tuna are generally in the range of 45–75 cm.

The year class represented by the mode of fish in the size range of about 25-30 cm in the Philippines/Indonesian domestic fisheries during 2018 appears to progress to a mode of 50-60 cm in the same fisheries during 2019 (and possibly also the purse seine associated catch in 2019). This year class may also be represented as the mode of 80 cm fish in the purse seine associated catch in 2020 (Figure 8.3.3).

The graphs for 2020 show potentially three distinct modes (i) at 25-30 cm for the Philippines/Indonesia domestic fisheries, (ii) around 80 cm for the purse seine associated fishery, and (iii) the typical broad mode at around 130-135 cm for the longline fishery.

Figure 8.3.3 Annual catches (no. of fish) of bigeye tuna in the WCPO by size (2cm intervals) and gear type, 2014–2020.

(green–longline; yellow–Phil-Indo archipelagic fisheries; light blue–purse seine associated; dark blue–purse seine unassociated)

Figure 8.3.4 Annual catches (MT) of bigeye tuna in the WCPO by size (2cm intervals) and gear type, 2014–2020.
 (green–longline; yellow–Phil-Indo archipelagic fisheries; light blue–purse seine associated; dark blue–purse seine unassociated)

8.4 SOUTH PACIFIC ALBACORE

Prior to 2001, south Pacific albacore catches were generally in the range 25,000–50,000 mt, with a significant peak in 1989 (49,076 mt) when driftnet fishing was in existence. Since 2001, catches have greatly exceeded this range, primarily as a result of the growth in several Pacific Islands domestic longline fisheries. The provisional **south Pacific albacore** catch in 2020 (69,931 mt), was the lowest since 2011 and around 23,000 mt less than the record catch taken in 2017 (93,835 mt).

Figure 8.4.1 South Pacific albacore catch (mt) by gear ("Other" is primarily catch by the driftnet fishery.)

In the post-driftnet era, **longline** has accounted for most of the South Pacific albacore catch (> 75% in the 1990s, but > 90% in recent years). The annual South Pacific Albacore **troll** catch (with a season spanning November–April) dropped from a range between 4,000–8,000 mt during the 1990s, to a range of 2,000–3,500 mt (Figure 6.1.1) over the past 10–15 years, although the 2020 troll catch (4,772 mt) was the highest since 2003. The provisional **WCP–CA albacore catch** for 2020 (105,4304 mt) was amongst the lowest catches over the last two decades and 43,000 mt lower than the record (148,051 mt in 2002). The **WCP–CA albacore catch** (which includes catches from fisheries in the North Pacific Ocean west of 150°W) typically contributing around 80% of the Pacific catch of albacore (provisional Pacific Ocean albacore tuna catch for 2020 is 124,774 mt).

The longline catch of albacore is distributed over a large area of the south Pacific (Figure 8.4.2) but concentrated in the west. The Chinese-Taipei distant-water longline fleet catch is taken in all regions, while the Pacific Island domestic longline fleet catch is restricted to the latitudes 10°–25°S. Troll catches are distributed in New Zealand's coastal waters, mainly off the South Island, and along the SCTZ. Less than 20% of the overall south Pacific albacore catch is usually taken east of 150°W.

Figure 8.4.2 Distribution of South Pacific albacore tuna catch, 1988–2020.

The four-region spatial stratification used in stock assessment is shown.

The longline fishery takes adult albacore in the narrow size range of 90–105 cm and the troll fishery take juvenile fish in the range of 45–80cm (Figure 8.4.3 and Figure 8.4.4). Juvenile albacore also appears in the longline catch from time to time (e.g. fish in the range 60–70 cm sampled from the longline catch). The size distribution in the south Pacific albacore catch for 2020 shows a clear mode of small albacore around 60cm from the troll fishery and slightly larger fish than for recent years in the longline fishery.

Figure 8.4.3 Annual catches (no. of fish) of albacore tuna in the South Pacific Ocean by size (2cm intervals) and gear type, 2014–2020. (green–longline; orange–troll)

Figure 8.4.4 Annual catches (MT) of albacore tuna in the South Pacific Ocean by size (2cm intervals) and gear type, 2014–2020. (green–longline; orange–troll);

8.5 SOUTH PACIFIC SWORDFISH

The distant-water Asian fleets (Japan, Chinese Taipei and Korea) accounted for most of the south Pacific swordfish catch from 1972 to the mid-1990s (Figure 8.5.1), with catches slowly increasing from 2,500 mt to about 5,000 mt. The development of target (domestic) fisheries in Australia and New Zealand accounted for most of the increase in total catch to around 10,000 mt in early 2000s, with burgeoning Pacific Island domestic fleets also contributing. The EU-Spanish longline fleet targeting swordfish (which account for most of the OTHER category in Figure 8.5.1) entered the fishery in 2004 and resulted in total swordfish catches increasing significantly to a new level of around 15,000 mt, and then to more than 20,000 mt over the period 2011-2018, with contributions from the distant-water Asian fleet catches. The provisional 2020 catch estimate for the South Pacific (18,410 mt) was similar to the 2019 catch but clearly lower than the record 2015 catch, mainly due to a reduction in distant-water Asian fleet catches (although 2020 estimates for some fleets were provisional at the time of writing this paper).

Figure 8.5.1 South Pacific longline swordfish catch (mt) by fleet

The catch of swordfish for the WCP-CA south of the equator (Figure 8.5.2) in 2020 was 5,373 mt, a continuation in the decline of annual catches since 2012 in each category of fleet, and the lowest since the late 1990s. As with other WCPFC fisheries, the impacts of COVID-19 were one of the reasons contributing to this decline, although the EU-Spanish fleet catch in 2020 (1,415 mt) was the highest since 2016.

Figure 8.5.2 WCP-CA (south of equator) longline swordfish catch (mt) by fleet

The longline catch of swordfish is distributed over a large area of the south Pacific (Figures 8.5.3 and A10). There are four main areas of catches (i) the far eastern Pacific Ocean off Chile and Peru, where most of the EU-Spanish fleet catch comes from but also some of the distant-water Asian catches; (ii) the south central Pacific Ocean region south of the Cook Islands and French Polynesia, predominantly covered by the EU-Spanish fleet; (iii) the coastal waters of New Zealand, Australia and adjacent Pacific Island countries (domestic fleets); and (iii) the equatorial Pacific Ocean between 130–160°W, covered by the distant-water Asian fleets.

Figure 8.5.3 Distribution of South Pacific longline swordfish catch, 1995–2020.

The swordfish caught throughout the South Pacific Ocean are generally in the range of 110–250 cm, with a mean around 180 cm (lower jaw-fork length – Figures 8.5.4 and 8.5.5). There is evidence of inter-annual variation in the size of swordfish taken by fleet and variation in the size of fish by fleet, for example, the EU-Spanish fleet generally catch larger swordfish than the distant-water Asian fleets, which could be related to area fished. Note the two modes of fish at around 140 cm and 180 cm in the 2019 size data (Figure 8.5.4). There were no size data collected for the EU-Spanish longline fleet during 2020 due to the impact of COVID-19 restrictions.

Figure 8.5.4 Annual catches (number of fish) of swordfish in the WCP-CA (south of the equator) by size (5cm intervals) and fleet, 2014–2020. (green–EU-Spanish fleet catch; yellow–distant-water Asian fleet catch; orange– Domestic fleets) 2020 data for EU-Spanish longline fleet are not available.

Figure 8.5.5 Annual catches (metric tonnes) of swordfish in the WCP-CA (south of the equator) by size (5cm intervals) and fleet, 2014–2020. (green–EU-Spanish fleet catch; yellow–distant-water Asian fleet catch; orange–Domestic fleets) 2020 data for EU-Spanish longline fleet are not available.

8.6 OTHER BILLFISH

8.6.1 Blue Marlin

Blue marlin are mainly taken by the longline gear in the tropical WCP-CA with relatively small amounts also taken by purse seine, troll, handline and a range of other small-scale gears (e.g. gillnet). WCP-CA catches of blue marlin have ranged from around 8,000–25,000 mt since the 1970s although there remains some uncertainty around some of the estimates by fleet and gear. The provisional **WCP-CA blue marlin catch** (11,900 mt) for 2020 is a clear decline compared

to recent years and the lowest since 1990 (Figure 8.6.1). T Figure 8.6.2 shows the distribution of longline-caught blue marlin highlighting that they are more prevalent in the western tropical waters of the WCP-CA (complete aggregate data stratified by area are not available for the other gears at this stage). The decline in the catch for 2020 may be related to the general decline in the longline catch in the areas where blue marlin are usually taken due to the impacts of COVID-19.

Figure 8.6.1 WCP-CA blue marlin catch (mt) by gear

Figure 8.6.2 Distribution of longline Blue marlin catch in the Pacific Ocean, 1990–2020.

8.6.2 Black Marlin

Black marlin are mainly taken by the longline gear in the tropical WCP-CA but also catches by purse seine, handline and a range of other small-scale gears (e.g. gillnet). WCP-CA catches of black marlin have ranged from around 1,300–3,800 mt since the early 1970s (when catches were at their highest), although there remains some uncertainty around some of the estimates by fleet and gear. The provisional **WCP-CA black marlin catch** (1,647 mt) for 2020 was similar to recent years, but slightly lower than the recent ten-year average (Figure 8.6.3). Figure 8.6.4 shows the distribution of longline-caught black marlin highlighting that their distribution does not extend to the eastern areas as much as blue marlin and they are clearly more prevalent in the western tropical waters of the WCP-CA, and to a lesser extent in the waters of PNG, Solomon Islands, New Caledonia and north-east Australia. Complete aggregate data stratified by area are not available for the other gears at this stage, but black marlin catches by Indonesia and Philippines handline and Vietnam gillnet overlap the main areas of the longline catch for this species.

Figure 8.6.3 WCP-CA black marlin catch (mt) by gear

Figure 8.6.4 Distribution of longline Black marlin catch in the Pacific Ocean, 1990–2020.

8.6.3 Striped Marlin

Striped marlin are mainly taken by the longline gear in the sub-tropical areas of the WCP-CA with minor catches by other gears, principally several gillnet fisheries. WCP-CA annual catches of striped marlin often exceeded 8,000 mt prior to 1990, with the gillnet fishery catch comprising a significant proportion of this catch during the 1970s. Since 2000, catches have been generally below 6,000 mt., although there remains some uncertainty around the availability and quality of estimates for some fleets and gears. Species identification is also acknowledged to be an issue in some fisheries.

WCP-CA striped marlin catch (3,492 mt) for 2020 was slightly lower than in 2019, but around the level of the recent ten-year average (Figure 8.6.5). Figure 8.6.6 shows the distribution of longline-caught striped marlin, with catches concentrated in the waters off the east coast of Japan, the Coral and Tasman Seas between eastern Australia, New Caledonia and New Zealand, and in the eastern areas, in and around Hawaii and French Polynesia. Complete aggregate data stratified by area are not available for the other gears at this stage.

Figure 8.6.5 WCP-CA striped marlin catch (mt) by gear

Figure 8.6.6 Distribution of longline Striped marlin catch in the Pacific Ocean, 1990–2020.

8.6.4 North Pacific Swordfish

Swordfish are mainly taken by the longline gear in the north Pacific Ocean with minor catches by other gears, including gillnet fisheries. Annual catches of north Pacific swordfish have generally exceeded 10,000 mt since 1972 (Figure 8.6.7). In recent years, the catches have been amongst the highest recorded (after the record catch in 1993), although there remains some uncertainty around the availability and quality of estimates for some fleets and gears, and these estimates have yet to be reconciled with estimates from the ISC¹³ and the IATTC¹⁴. The provisional **North Pacific swordfish**

catch (11,744 mt) for 2020 was a clear decline on catches in recent years and the lowest since 2011 (Figure 8.6.7). As with the 2020 blue marlin catch, the decline in the North Pacific swordfish catch for 2020 may be related to the general decline in the longline catch in the areas where swordfish are usually taken due to the impacts of COVID-19.

Figure 8.6.7 North Pacific Swordfish catch (mt) by gear

Figure 8.6.8 shows the distribution of longline-caught swordfish in the Pacific Ocean, with catches concentrated across the Pacific Ocean, north of 20°N, including the waters off the east coast of Japan, and adjacent to the Hawaii EEZ. Swordfish catches in the north Pacific Ocean are also prevalent in Indonesia and in the waters bounded by China, Chinese Taipei, Philippines and Vietnam. Complete aggregate data stratified by area are not available for the other gears at this stage.

Figure 8.6.8 Distribution of longline swordfish catch in the Pacific Ocean, 1990–2020.

¹³ ISC – The International Scientific Committee for Tuna and Tuna-like Species in the North Pacific Ocean

¹⁴ IATTC – Inter-American Tropical Tuna Commission

8.7 NORTH PACIFIC ALBACORE

Albacore tuna are mainly taken by the longline, pole-and-line and troll gears in the north Pacific Ocean, with minor catches by purse seine; albacore tuna was also the target of the driftnet fishery in the 1980s. Annual catches of North Pacific albacore have fluctuated since the 1950s, with peak periods in the 1970s and then again in the late 1990s into the early 2000s (Figure 8.7.1). In recent years, catches have been lower, due to declines in the pole-and-line and longline catches. There remains some uncertainty around the availability and quality of estimates for some fleets and gears, and these estimates have yet to be reconciled with estimates from the ISC and the IATTC. **North Pacific albacore catch** (54,843 mt) for 2020 was lower than the 2019 catch (Figure 8.7.1), but on a similar level to the recent five-year average.

Figure 8.7.1 WCP-CA North Pacific Albacore catch (mt) by gear

8.8 NORTH PACIFIC BLUEFIN

Bluefin tuna are mainly taken by the purse seine gear in the north Pacific Ocean with minor catches from the longline, troll and by other small-scale gears in Japan waters; there have also been significant historic catches from the troll and pole-and-line gears. Annual catches of north Pacific bluefin tuna have fluctuated since the 1970s, with peak periods in the early 1980s and for certain years in the mid-late 1990s and into the first decade of 2000s (Figure 8.8.1). Catches declined in the period 2012–2015 but have increased in recent years. There remains some uncertainty around the availability and quality of estimates for some fleets and gears, and these estimates have yet to be reconciled with estimates from the ISC and the IATTC. **North Pacific bluefin tuna catch** (13,464 mt) for 2020 was the highest since 2017 and on a similar level to the recent five-year average (Figure 8.8.1), but clearly lower than the long-term average catch.

Figure 8.8.1 North Pacific Bluefin catch (mt) by gear

APPENDIX - ADDITIONAL INFORMATION

ALL FISHERIES – Additional Information

Figure A1. Catch estimates (mt) of the tropical tuna species (albacore, bigeye, skipjack and yellowfin) in the WCP-CA, by archipelagic waters (AWs), national waters (EEZs, excluded AWs) and the high seas for all gear types combined.

LOGLINE FISHERY – Additional Information

Figure A2. Monthly WCPFC longline fishery effort (VMS fishing days and 100s of Hooks, 2015-2021
(WCPFC Area; Longline Fishery Effort only considers VMS and logbook effort data for the main domestic, domestic-based foreign and distant-water fleets where VMS data with high coverage are available consistently over recent years)

Figure A3. Cumulative South Pacific Albacore longline fishery effort by month, 2016-2021, as measured by VMS

(WCPFC Area south of 10°S; VMS estimated fishing days; only includes VMS data for the main domestic, domestic-based foreign and distant-water fleets where VMS data have been provided with high coverage consistently over recent years)

Figure A4. Cumulative Tropical longline fishery effort by month, 2016-2021, as measured by VMS

(WCPFC Area 20°N–10°S, 130°E–150°W; VMS estimated fishing days; only includes VMS data for the main domestic, domestic-based foreign and distant-water fleets where VMS data have been provided with high coverage consistently over recent years)
